Fire Ratings

of Archaic Materials and Assemblies
PATH (Partnership for Advancing Technology in Housing) is a new private/public effort to develop, demonstrate, and gain widespread acceptance for the "Next Generation" of American housing. Through the use of new and innovative technologies the goal of PATH is to improve the quality, durability, environmental efficiency, and affordability of tomorrow's houses.

Initiated at the request of the White House, PATH is managed and supported by the U.S. Department of Housing and Urban Development. In addition, all Federal Agencies that engage in housing research and technology development are PATH partners, including the Department of Energy, the Department of Commerce, the Environmental Protection Agency, and the Federal Emergency Management Agency. State and local governments and other participants in the public sector also are partners in PATH. Product manufacturers, home builders, insurance companies, and lenders represent private industry in the PATH partnership.

To learn more, please contact: PATH, Suite B133, 451 Seventh Street, S.W., Washington, D.C. 20410; fax 202-708-4250; e-mail pathnet@pathnet.org.

The statements and conclusions contained in this publication are those of the National Institute of Building Sciences and do not necessarily reflect the view of the Department of Housing and Urban Development. The Institute has made every effort to verify the accuracy and appropriateness of the publication’s content. However, no guarantee of the accuracy or completeness of the information or acceptability for compliance with any industry standard or mandatory requirement of any code, law, or regulation is either offered or implied.
Foreword

Older buildings often contain materials that are fire safe but not listed in current fire ratings sources. This lack of documentation hinders the modernization and reuse of our nation’s building stock. The Guideline on Fire Ratings of Archaic Materials and Assemblies is a compilation of fire ratings from earlier sources for a wide variety of materials and assemblies found in buildings from the nineteenth to the mid-twentieth centuries. This guideline also provides methods for calculating the fire resistance of general classes of archaic materials and assemblies for which no documentation can be found.

First published in 1980, this guideline has found widespread use and acceptance among architects, engineers, preservationists, and code officials. It has been incorporated into numerous state and local building codes, three model code publications, and two NFPA standards.

Now, for the Partnership for Advancing Technology in Housing (PATH) program, the Guideline on Fire Ratings of Archaic Materials and Assemblies has been updated to reflect changes in assessment techniques and to provide additional information on doors. HUD is pleased to reissue this important and time-tested publication, knowing that it will remain a valuable resource for preserving and reusing our nation’s housing and building stock.

Susan M. Wachter
Assistant Secretary for Policy Development and Research
Acknowledgments

The National Institute of Building Sciences produced the first edition of the Guideline on Fire Ratings of Archaic Materials and Assemblies in 1980, with Brady Williamson the principal author and Joseph Zicherman, Fred Fisher, and Harry Hasegawa coauthors. Reviewers were Herman Spaeth, Anne Watson, Vytenis Babrauskas, Norman Kornsand, Harold Nelson, Richard Bletzacker, and Russell Parks. Project managers were Robert Kapsch of HUD and William Brenner of NIBS. Technical managers were David Hattis and Howard Markman of Building Technology, Inc.

NIBS produced this updated edition in 1999, with Joseph Zicherman the principal consultant. Reviewers were Jack Watts, Caroline Alderson, Paul Armstrong, and Harold Olin. Project managers were Nelson Carbonell of HUD and William Brenner of NIBS. The technical manager was David Hattis of Building Technology, Inc., and the graphic designer was Marcia Axtmann Smith. NFPA provided an electronic version of the tables and illustrations in Appendix A. The material in Appendix B is used with the permission of English Heritage.

Introduction

The purpose of the Guideline on Fire Ratings of Archaic Materials and Assemblies is to assist architects, engineers, preservationists, and code officials in evaluating the fire safety of older buildings by providing documentation on the fire-related performance of a wide variety of archaic building materials and assemblies, and, for those cases where documentation cannot be found, by providing ways to evaluate general classes of archaic materials and assemblies. The term "archaic" encompasses materials and assemblies typical of an earlier time and no longer in common use. "Fire-related performance" includes fire resistance, flame spread, smoke production, and combustibility.¹

The Guideline assumes that the building elements being evaluated—as well as their fastening, joining, and incorporation into the building structure—are mechanically sound. The user must make a determination that the original materials and the manner in which they were installed are in good condition and have not been weakened by age or deterioration. Such an assessment may be difficult because process and quality control were not good in many industries and variations among locally available raw materials and manufacturing techniques often resulted in products or installations that varied considerably in strength and durability. The properties of iron and steel, for example, exhibited great variation depending on the mill and the process used.

With this caveat, there is nothing inherently inferior about archaic materials or construction techniques. The pressures that promote changes in construction are most often economic and technological—matters not necessarily related to safety. The high cost of labor made wood lath and plaster uneconomical. The high cost of land and the congestion of cities provided the impetus for high-rise construction, and improved technology made it possible. The difficulty with archaic materials and assemblies is not a question of suitability, but familiarity, and the question of their continued use is usually not based on their fire performance but on the lack of sufficient documentation related to that performance. Lacking documentation, the building official may require a full-scale fire test or the removal of the construction in question. Both alternatives are time consuming, wasteful, and destructive of the historic fabric of the building.

Modern building codes state the fire performance of key building elements—such as walls, floor/ceiling assemblies, doors, and shaft enclosure—in performance terms, as hours of fire resistance. It does not matter whether these elements were built in 1850 or 2000, only that they provide the degree of fire resistance required by local building regulations. This Guideline is intended to provide a basis for the continued acceptance of archaic materials and assemblies that otherwise meet modern fire performance requirements.

1 Fire-Related Performance of Archaic Materials and Assemblies

1.1 Fire Performance Measures

This Guideline does not specify the levels of fire performance required for building components. These are controlled by the building's occupancy and use as set forth in local building regulations, which require specific building components or assemblies such as walls, floor/ceilings, and doors to be

¹ For information on other fire-related aspects of older buildings, see the Preservation Briefs and Preservation Tech Notes series published by the Preservation Assistance Division, National Park Service, U.S. Department of Interior. These publications are available online at www2.cr.nps.gov/tps.
characterized in terms of "fire resistance" and require exposed materials to be characterized in terms of "flame spread."

Fire resistance and flame spread are fundamentally different parameters, affecting life and property safety in different ways. Fire resistance relates to structural fire performance and becomes important only after a fire has become established and threatens a building's structural integrity. Flame spread relates to the potential for fire growth within a structure. Properties related to flame spread are most important in the early stages of a fire and usually measure the performance of exposed or "finish" materials within building spaces.

For archaic materials, flame spread properties, unlike fire resistance properties, generally can be deduced through the examination of materials, through testing according to ASTM E 84, or other methods. Published data for the flame spread properties of specific assemblies is limited; however, except for recent products listed in handbooks.

The mitigation or treatment of potential problems related to flame spread (for example, the removal of suspect or defective finish materials, or their treatment with an appropriate coating or low flame spread finish) will generally cost less than the treatment of fire resistance deficiencies since the latter may affect large numbers of door assemblies or entire building structural systems.

The fire resistance of a given building element is established by subjecting a sample of the assembly to a "standard" fire test to determine its fire resistance. This is essentially its resistance to destruction (i.e., specified loss of function) throughout a prescribed time period in a fully developed fire. The test follows a "standard" time-temperature curve derived from a methodology that has changed little since the 1920s. The fire resistance test results tabulated in Appendix A have been reviewed and conservatively adjusted to reflect criteria found in the currently accepted versions of consensus-based standard fire resistance test methods.

Flame spread and smoke production, not always tested for in earlier years, are measured according to the ASTM E 84 test method. Archaic materials evaluated for these properties generally can be assumed to fall within a well-known range of values because the principal combustible component of these materials is cellulose. Smoke production, expressed as smoke density, continues to be important today. Early flame spread tests, developed in the 1940s, included a test for smoke density (104).

Plastics, one of the most important classes of contemporary materials, were not found in the review of archaic materials. If plastics are to be used in a rehabilitated building, they should be evaluated by contemporary standards. Information and documentation of their fire-related properties and performance is widely available.

Flame spread and smoke density are discussed below. Test results for eight common species of lumber, published in an Underwriter's Laboratories' report of 1952 (104), are reproduced in Figure 1. Similar data can also be found in the USDA Forest Service, Wood Handbook (Agriculture Handbook 72), available online at www.fs.fed.us.

Flame Spread

For regulatory purposes, the flame spread of interior finishes is most often measured using the ASTM E 84 "tunnel test." This test measures how far and how fast flames spread across the surface of the test sample. The resulting flame spread rating (FSR) is expressed as a number on a continuous scale where cement-asbestos board is 0 and red oak is 100 (materials with a flame spread greater than red oak have a FSR greater than 100.) The scale is divided into distinct groups or classes. The most commonly used flame spread classifications are:

2 Other accepted standard test methods for assessing fire growth characteristics related to flame spread of finish materials include room fire tests. These may be useful for conducting evaluations of finish materials under the alternative materials and methods provisions of adopted codes in lieu of providing tunnel test data. Such test methods are typified by ASTM E 603, Standard Guide for Room Fire Experiments, as well as NFPA 265 and UBC Standard 8-2, both of which provide a "Test Method for Evaluating Room Fire Growth Contribution of Textile Wall Covering."
Class I or A, with a 0–25 FSR

Class II or B, with a 26–75 FSR

Class III or C, with a 76–200 FSR

These classifications are typically used in modern building codes to restrict the rate of early fire spread on material surfaces. Since they differ, not all classes of materials can be used in all places throughout a building. For example, the flame spread of interior finishes in vertical exit ways or corridors leading to exits is more strictly regulated than are finishes in private dwelling units.

In general, inorganic archaic materials such as brick and tile can be expected to be in Class I. Materials of whole wood are mostly Class II or the lower end of Class III, although the thickness of specific products is important. For example, thin plywood or wood-grained particle board panels reconstituted from whole wood and based on a given wood species will generally have higher flame spread properties than those based on the original wood species tested as a thicker specimen. This effect needs to be considered in making design decisions.

Whole wood is defined as wood used in the same form as sawn from the tree. This is in contrast to contemporary reconstituted wood products such as plywood, fiberboard, hardboard, particle board, and oriented-strand board (OSB). If a combustible archaic material such as a non-fire retardant ceiling tile is not fabricated from whole wood, its flame spread classification could be well over 200 and thus would be particularly unsuited for use in exits and other critical locations in a building. Some plywoods and various wood fiberboards have flame spreads over 200. Although they can be treated with fire retardants to reduce their flame spread, it would be advisable to assume that all such products have a flame spread of over 200 unless there is information to the contrary.

### Smoke Density

The measurement of the density of smoke produced is specifically part of the ASTM E 84 tunnel test procedure. For the eight species of lumber shown in Figure I, the highest levels are 275–305 for yellow pine, but most of the others are less smoky than red oak, which has an index of 100. With the exception of values observed for some wood composites, the smoke values listed in Figure 1 are well below the general limitation of 450 adopted by most building codes.

#### 1.2 Combustible Construction Types

One of the earliest forms of timber construction used exterior load-bearing masonry walls with masonry columns or timber posts supporting timber beams and floors in the interior of the building. This form of construction, often called "mill" or "heavy timber" construction, displays fire resistance in excess of one hour. The exterior masonry walls will generally contain the fire within the building.

With the development of dimensional lumber, there was a switch from heavy timber to "balloon frame" construction. The balloon frame uses load-bearing exterior wood-frame walls with long studs that often extend from foundation to roof. When long studs became scarce, another form of construction, the "platform frame," replaced the balloon frame. This occurred...
from the 1850s to the 1920s in different areas of the country, depending on the supply of long studs. If information on the initial construction date of a wood-framed building is known, along with information about local practices followed at the time of construction, the likelihood that a building includes balloon framing may be assessed and addressed.

The difference between the two systems is significant because platform framing is automatically fire-blocked at every floor, while balloon framing commonly has concealed spaces that extend unblocked from basement to attic. The architect, engineer, and code official must be alert to the presence of such construction details because of the ease with which fire can spread in concealed building spaces. Requirements for fire blocking and fire stopping and allowances for combustible and noncombustible concealed spaces are set forth in local building regulations.

2.1 Preliminary Evaluation

The preliminary evaluation should begin with a building survey to note existing materials, the general arrangement of the structure, the use of occupied spaces, and the details of construction. The designer needs to know "what is there" before a decision can be reached about what to keep, what to remove, and what to upgrade during the rehabilitation process.

The evaluation must take into account the former and projected uses of the building and modifications to its mechanical, plumbing, and electrical systems. Seismic events, fires, and other accidents as well as non-conforming alterations must be researched. Finally, archaic materials and assemblies must be evaluated against applicable code requirements.

Two possible sources of information helpful in the preliminary evaluation are the original building plans and the building code in effect at the time of original construction. Plans may be on file with the local building department or in the offices of the original designers or their successors. If plans are available, the investigator should verify that the building was constructed according to the plans and whether or not the plans have been modified to include later alterations. Earlier editions of the local building code may be on file in the building department. The code in effect at the time of construction will contain fire performance criteria under which the original building was constructed. While this is no guarantee that the required performance was actually provided, it does give the investigator some guidance as to the level of performance that may be expected. Current code administration procedures and enforcement practices will define whether the requirements of the code in effect at the time of construction comply with currently required levels of performance.

Figure II illustrates one method for organizing preliminary field notes, with space provided for noting the materials, dimensions, and condition of the principal building elements. Each floor of the structure should be visited. In practice, there will often be identical materials and construction on every floor, but any exceptions may be of vital importance. A schematic diagram should be prepared for each floor showing the layout of exits and hallways and indicating where each element described in the field notes fits into the
structure as a whole. The locations of stairways and elevators should be clearly marked on the drawings. All exterior means of escape should be identified. The exact arrangement of interior walls is of secondary importance from a fire safety point of view and need not be shown on the drawings unless they are required by code.

The following notes explain the entries in Figure II.

**Exterior Bearing Walls.** Many old buildings utilize exterior walls to support the floor/ceiling assemblies at the building perimeter. There may be columns or interior bearing walls within the structure, but the exterior walls and their fire resistance are an important factor in assessing the building's fire safety. Note how the floor/ceiling assemblies are supported at their interface with the exterior walls of the building. If columns are incorporated in the exterior walls, the walls may be considered nonbearing.

**Exterior Nonbearing Walls.** The fire resistance of exterior walls is an important factor for two reasons. These walls (both bearing and non-bearing) are depended upon to contain a fire within the building of origin, or to keep a fire originating outside of a building from igniting that building either on the exterior or the interior. It is, therefore, important to indicate on the drawings the location and construction of all windows, doors, shutters, and other openings as well as the thickness and framing of any wired glass. The protection of openings adjacent to and potentially affecting any exterior means of egress, such as exterior stairs and fire escapes, is also important. The ground floor drawing should locate the building on the property and indicate precise distances to adjacent buildings.

**Interior Bearing Walls.** It may be difficult to tell whether or not an interior wall is load bearing, but the field investigator should attempt to make this determination. At a later stage of the rehabilitation process, this question will need to be answered exactly. Therefore, the field notes should be as accurate as possible.

**Interior Nonbearing Walls (Partitions).** A partition is a "wall that extends from floor to ceiling and subdivides space within any story of a building" (48). Besides providing for general separation of spaces within buildings, partitions also may have fire safety functions that entail specific fire resistance requirements. Examples include party walls, occupancy separations, smoke barriers, and corridor and exit enclosures. These must be clearly identified and may include fire-rated walls that provide the same functions. When such walls enclose a means of egress, the required flame spread properties of finish materials also must be accounted for.

Figure II includes categories for several types of walls. Since under some circumstances a building may have only one type of wall construction and in others it may have several, the occurrence and function of walls must be carefully noted and evaluated.

The field investigator should be alert for differences in function as well as in materials and construction details. In multiunit buildings, for example, wall details within apartments generally are not as important as the functions of separation walls or walls along defined egress paths and stairwells.

The preliminary field investigation should attempt to determine the thickness of all walls. A term introduced below called "thickness design" will depend on an accurate (± 1/4 inch) determination of thickness. Even though this initial field survey is called "preliminary," the data generated should be as accurate and complete as possible.

The field investigator should note the exact location from which his or her observations are recorded. For instance, if a hole is found through a stairwell wall that allows a cataloguing of the construction details, the field investigation notes should reflect the location of the "find." At the preliminary stage it is not necessary to core walls, since the interior details of construction usually can be determined at some location.
Structural Frame. There may or may not be a complete skeletal frame, but usually there are columns, beams, trusses, or similar elements. The dimensions and spacing of the structural elements should be measured and indicated on the drawings. For instance, if 10-inch-square columns are located on a 30-foot-square grid throughout the building, this should be noted. The structural material and its protective covering, if any, should be identified wherever possible. The thickness of the cover materials should be determined to an accuracy of ±1/4 inch. In a case in Chicago, local code officials found that in many older buildings slated for renovation, original wood timber columns had been replaced by nonfire-rated metal columns, degrading the structure's potential fire endurance. The performance of the metal columns was readily upgraded, however, by providing fire resistive cladding to achieve the required hourly fire ratings.

Floor/Ceiling Structural Systems. A sketch of the cross section of the structural system should be made. If there is no location where accidental damage has opened the floor/ceiling construction to visual inspection, it is necessary to make such an opening. An evaluation of the fire resistance of a floor/ceiling assembly requires detailed knowledge of the materials and their arrangement. Special attention should be paid to the cover on structural steel elements and the nature and condition of suspended ceilings and similar membranes.

Roofs. If it is apparent that the roof is sound for ordinary use and can be retained in the rehabilitated building, it then becomes necessary to evaluate its fire performance. The field investigator must measure the thickness and identify the types of materials that have been used. Be aware that there may be several layers of roofing materials present and that the number may be limited by the local building code.

Doors. Doors to corridors and exits represent some of the most important fire resistive elements within a building. The uses of the spaces separated by the doors largely controls the level of fire performance necessary. Walls and doors enclosing stairs or elevator shafts normally require a higher level of performance than between a bedroom and bath. The various uses are differentiated in Figure II. Careful measurements of the thickness of door panels must be made and the type of core material within each door must be determined. Note whether doors have self-closing devices and check the general operation of the doors. Latches should engage and doors should fit tightly in the frame. Hinges should be in good condition. Identify any door glazing and note its framing material.

Materials. The field investigator should be able to identify commonly found building materials in a given geographic area. In situations where an unfamiliar material is found, a sample should be obtained.

Thickness. The thickness of all materials should be measured accurately since under most circumstances anticipated levels of fire resistance are very sensitive to the material thickness.

Condition. The method of attaching the various layers and facings to one another or to the supporting structural element should be noted under the appropriate building element. The "secureness" of the attachment and the general condition of the layers and facings also should be noted.

Notes. The "Notes" column can be used for many purposes, including providing specific references to other field notes or drawings, such as those describing the occupancy of the building or space and the functions of its components.

After the building survey is completed, the data collected must be analyzed. A suggested work sheet for organizing this information is shown in Figure III.

Requirements for fire resistance and the flame spread properties of each building element are normally established by the local building code. The fire performance of the existing materials and assemblies should be estimated using one of the...

*Figure II. Preliminary Evaluation Field Notes*
techniques described below. If the fire performance of the existing building element(s) is equal to or greater than that required, the materials and assemblies may be considered acceptable as they are. If the fire performance is less than required, corrective measures must be taken.

The most common methods of upgrading the level of protection are either the removal and replacement of the existing building elements or repairing and upgrading them. Other fire protection measures, such as automatic sprinklers or detection and alarm systems, also can be considered, but they are beyond the scope of this Guideline. If the upgraded protection is still less than that required or deemed to be acceptable, additional corrective measures must be taken. This process must continue until a level of performance acceptable to the building authority and consistent with good practice is achieved.

2.2 Fire Resistance of Existing Building Elements

The ability of the existing building elements to sustain a standard fire test exposure for a prescribed period, generally referred to as its fire endurance or fire resistance, can be estimated from the tables and histograms contained in Appendix A, which is organized by type of building element: walls, columns, floor/ceiling assemblies, beams, and doors. Within each building element, the tables are organized by type of construction, such as masonry, metal, or wood frame, then further divided by minimum dimensions or the thickness of the building element.

A histogram precedes every table that has ten or more entries. Its X-axis measures fire resistance in hours and its Y-axis shows the number of entries in that table having a given level of fire resistance. The histograms also contain the location of each entry within the table for easy cross referencing.

Because they are keyed to the tables, the histograms usually can be used to speed the preliminary investigation. For example, Table 1.3.2, "Wood Frame Walls 4" to Less Than 6" Thick," contains 96 entries. Rather than study each table entry, the designer can examine the histogram, which shows that every wall assembly listed in that table has a fire resistance of less than two hours. If the building code required the wall to have 2-hour fire resistance, the designer, with a minimum of effort, is made aware of a problem that requires closer study.

Suppose the code had only required a wall of 1-hour fire resistance. The histogram shows far fewer complying elements—19—than noncomplying ones—77. If the existing assembly is not one of the 19 complying entries, there is a strong possibility it is deficient. The histograms also can be used in the converse situation: if the existing assembly is not one of the smaller number of entries with a lower than required fire resistance, there is a strong possibility the existing assembly will be acceptable.

At some point, the existing building component or assembly must be located within the tables. If not, its fire resistance must be determined through one of the other techniques presented herein. Locating the building component in the tables in Appendix A not only documents the accuracy of its fire resistance rating, but provides a source of that documentation for the building official.

2.3 Effects of Openings and Penetrations in Fire Resistant Assemblies on Fire Endurance and Fire Resistance Ratings

There are often features of wall or floor/ceiling components that were not included in the original building design or that were not included in fire tests, including doors and windows, glazed transoms and other types of glazing in corridors, shaftways, through penetrations, and membrane penetrations for utilities such as plumbing, electrical, and communications services.

Building codes generally use the terms "openings" and "opening protection" to refer to doors and window openings. Conversely, the term "penetrations" typically

*Figure III. Preliminary Evaluation Worksheet*
refers to passages for mechanical or electrical services for traversing assemblies found in a building. Each requires a different fire resistance test method to be evaluated, and each generates different information.

The most common examples of penetrations are pipes and utility wires passed through holes poked through an assembly. Their performance will have been qualified for use in new buildings by testing according to the ASTM E 814, Standard Test Method for Fire Tests of Through-Penetration Fire Stops, and its derivative standards promulgated by ANSI and NFPA. During the life of the building, however, many penetrations may have been added, and by the time a building is ready for rehabilitation it is not sufficient just to consider the fire resistance of the assembly as originally constructed.

It is also necessary to consider all classes of penetrations and openings and their relative impact upon fire performance. For instance, the fire resistance of a corridor wall may be less important in a given building application than the effect of plain glass being present in doors or transoms since the latter will lead to very early failures. Generally speaking, a building's doors and associated installation features (hardware, frames, transoms, and glazing) represent the most important single class of openings having a crucial fire safety function that needs to be addressed.

A fully developed fire generates substantial quantities of heat and gaseous fuels capable of penetrating unprotected openings or non-fire-stopped holes that might be present in the walls or floors and ceilings of a fire-affected compartment. The presence of such unprotected openings and penetrations can lead to a severe degradation of the fire resistance of those building elements and to a greater potential for fire spread. This is particularly true for penetrations located high in a compartment where the positive pressure of the fire can force unburned gases through such a penetration.

Unprotected penetrations in a floor/ceiling assembly will generally completely negate the barrier qualities of the assembly and will lead to rapid spread of fire to the space above. It will not be a problem, however, if the penetrations are filled with noncombustible or other fire-rated materials adequately attached to the structure. The threat to the upper two-thirds of walls exposed to fire will be similar to that experienced by the floor/ceiling assemblies undergoing a fire exposure from below. This is because a positive pressure can be reasonably expected to be present in the top of any room exposed to a fully developed fire, and such an exposure can be expected to push hot and burning gases through any penetrations present unless they are completely sealed. In the same context, the performance of all components related to HVAC systems present in buildings (as well as mechanical or electrical/communication systems whose components are associated with fire resistive assemblies or components) must be carefully considered. Materials available to mitigate these potential problems include listed intumescent and other insulating firestopping materials, systems, and assemblies as found in listing handbooks from approved third party laboratories.

Building codes require doors installed in fire resistive walls to resist the passage of fire for a specified period of time. If the door to a room with a fully developed fire is not closed, a large plume of fire will typically escape through the doorway, preventing anyone from using the space outside the door while allowing the fire to spread. This is why the presence of effective door closers and an absence of obstacles to the timely closing of fire doors in an emergency are so important.

Glass in doors and transoms can be expected to shatter rapidly unless constructed of listed or approved wired glass in a steel frame or other contemporary fire-rated glazing products now available. As with other building elements, non-firestopped penetrations or nonrated openings including those created by windows and transoms must be upgraded or otherwise protected.

As part of ongoing rehabilitation efforts in older buildings, significant research directed at upgrading the fire resistance of
existing door, transom, and sidelight assemblies has taken place in the United States and Great Britain. An English Heritage Technical Guidance Note on this subject (166) treats this problem comprehensively and includes information for upgrading wood panel doors. Because the fire test protocols utilized in Britain for doors are based on British Standard 476, which provides an equivalent fire exposure to similar U.S. test methods, the results presented in the English Heritage Technical Guidance Note can be used directly in American applications.

In the United States, efforts to upgrade door performance have been underway under the auspices of the General Services Administration as part of an effort to preserve the historic components of its older structures. This has resulted in the successful fire testing of retrofitted door assemblies using contemporary glazing products and associated materials.

In the United States, efforts to upgrade door performance have been underway under the auspices of the General Services Administration as part of an effort to preserve the historic components of its older structures. This has resulted in the successful fire testing of retrofitted door assemblies using contemporary glazing products and associated materials.

Table 5.1 in Appendix A contains 42 entries describing the fire endurance of doors mounted in sound, tight-fitting frames. Appendix B contains 28 treatments for upgrading the fire resistance of wood panel doors from the above-mentioned English Heritage Technical Guidance Note. Section 3.4, below, outlines one procedure for the evaluation and possible upgrading of existing doors.

3
Final Evaluation and Design Solution

The final building evaluation begins after the rehabilitation project has reached the final design stage and the choice has been made to retain certain archaic materials and assemblies. By this point, the specific fire resistance and flame spread requirements will have been determined for the project. This may involve having the local building and fire officials review the field drawings and evaluations recorded in the worksheets in Figures II and III.

If the materials and assemblies in question are listed in Appendixes A or B, their fire resistance can be determined immediately. If not, two other approaches can be used, one experimental, the other theoretical.

3.1
The Experimental Approach

This approach involves conducting an appropriate fire test(s) to determine directly the material or assembly's fire-related properties. Such testing must utilize ASTM E 84, Test Method for Surface Burning Characteristics of Building Materials (flame spread), and ASTM E 119, Test Methods for Fire Tests of Building Construction and Materials (fire resistance). Both test methods require significant amounts of sample for testing so other approaches, as outlined later, should also be investigated. There are a number of laboratories in the United States that routinely conduct such fire tests; a current list can be obtained by contacting one of the model code organizations or the National Fire Protection Association.

A contract with a testing laboratory for a specific project should require the laboratory's observation (or that of a registered engineer acceptable to the building official) of the specimen's preparation and testing. A complete description of where and how the specimen was obtained from the building, the transportation of the specimen, and its preparation for testing should be noted in detail so that the building official can be satisfied that the fire test is representative of the actual use. Photographic or video documentation are especially helpful in this regard.

The test report should describe the fire test procedure and the response of the material or assembly. The laboratory usually submits a cover letter with the report to describe the provisions of the fire test that were satisfied by the material or assembly under investigation. The building official generally will require such a cover letter but will also read the report to confirm that the material or assembly meets code requirements. Local code officials should be kept informed of all details of the testing process.

The experimental approach can
be costly and time consuming because specimens must be taken from the building and transported to the testing laboratory. For testing of flame spread of finish materials by ASTM E 84, testing will require a sample two feet wide and 25 feet long, which may be taken in three sections. For testing by ASTM E 119 of a load-bearing assembly that has continuous reinforcement, the test specimen must be removed from the building, transported, and tested in one piece.

In special cases, a "nonstandard" small-scale test may be used with the concurrence of the building official for fire endurance testing. Sample sizes need only be 10 to 25 square feet, while full-scale tests require test samples of either 100 or 180 square feet in size. The small-scale test is best suited for testing non-load bearing assemblies against thermal transmission only.

For alternates to flame spread testing according to ASTM E 84, consider the methods described in the next section.

### 3.2 The Theoretical Approach

Theoretical methods offer an alternative to the full-scale fire tests discussed above. For example, most codes allow alternate materials and methods to be used based on test data and engineering analyses in lieu of full-scale tests. These analyses may draw upon computer simulation and mathematical modeling, thermodynamics, heat-flow analysis, and materials science to predict the fire performance of a material or assembly.

Where properties other than fire endurance are concerned, the evaluation of materials for heat release through the use of cone calorimeter techniques (see ASTM E 1354) or through use of the intermediate scale calorimeter "ICAL" (see ASTM E 1623) may be appropriate. Such an evaluation can be included as one component of a fire hazard analysis conducted for review by the code official for a given project design. The evaluation of flame spread by the LIFT (linear ignition and flame travel) apparatus (see ASTM E 1321) or room fire testing of unusual or poorly characterized finish materials based on the techniques found in ASTM E 603, cited earlier, also may be of use.

#### Harmathy’s Ten Rules of Fire Endurance Rating

**Rule 1: The "thermal" fire endurance of a construction consisting of a number of parallel layers is greater than the sum of each "thermal" fire endurance that is characteristic of the individual layers when exposed separately to fire.**

The minimum performance of an untested assembly can be estimated if the fire endurance of the individual components is known. Though the exact rating of the assembly cannot be stated, the endurance of the assembly is greater than the sum of the endurance of the components. This rule can be exemplified by the fact that the fire endurance of multiple sheets of gypsum wallboard, such as those of other fire-rated materials, will exceed the fire endurance of individual fire-rated slabs of the same total thickness.

When a building assembly or component is found to be deficient, the fire endurance can be upgraded by providing a protective membrane. This membrane could be a new layer of brick, plaster, or drywall. The fire endurance of this membrane is called the "finish rating." Tables 1.5.1 and 1.5.2 in Appendix A contain the finish ratings for the most commonly employed materials (see also the notes to Rule 2).

The test criteria for the finish rating is the same as for the thermal fire endurance of the total assembly: average temperature increases of 250°F above

---

3 The "thermal" fire endurance is the time at which the average temperature on the unexposed side of a construction exceeds its initial value by 250°F when the other side is exposed to the "standard" fire specified by ASTM Test Method E 119.
ambient or 325°F above ambient at any one place with the membrane being exposed to the fire. The temperature is measured at the interface of the assembly and the protective membrane.

**Rule 2: The fire endurance of a construction does not decrease with the addition of further layers.**

Harmathy notes that this rule is a consequence of the previous rule. Its validity follows from the fact that the additional layers increase both the resistance to heat flow and the heat capacity of the construction. This, in turn, reduces the rate of temperature rise at the unexposed surface.

This rule is not just restricted to "thermal" performance but affects the other fire test criteria: direct flame passage, cotton waste ignition, and load bearing performance. This means that certain restrictions must be imposed on the materials to be added and on the loading conditions. One restriction is that a new layer, if applied to the exposed surface, must not produce additional thermal stresses in the construction, i.e., its thermal expansion characteristics must be similar to those of the adjacent layer. Each new layer must also be capable of contributing enough additional strength to the assembly to sustain the added dead load. If this requirement is not fulfilled, the allowable live load must be reduced by an amount equal to the weight of the new layer. Because of these limitations, this rule should not be applied without careful consideration.

Particular care must be taken if the material added is a good thermal insulator. Properly located, the added insulation could improve the "thermal" performance of the assembly. Improperly located, the insulation could block necessary thermal transmission through the assembly, thereby subjecting the structural elements to greater temperatures for longer periods of time, and could cause premature structural failure of the supporting members.

Under this rule, the addition of new components, such as EIFS systems, must be evaluated with care where they can affect fire performance.

**Rule 3: The fire endurance of constructions containing continuous air gaps or cavities is greater than the fire endurance of similar constructions of the same weight, but containing no air gaps or cavities.**

Voids in a construction provide additional resistance in the path of heat flow. Numerical heat flow analyses indicate that a 10 to 15 percent increase in fire endurance can be achieved by creating an air gap at the midplane of a brick wall. Since the gross volume is also increased by the presence of voids, the air gaps and cavities have a beneficial effect on stability as well. However, constructions containing combustible materials within an air gap may be regarded as exceptions to this rule because of the possible development of burning in the gap.

There are numerous examples of this rule in the tables. For instance:

**Table 1.1.4; Item W-8-M-82:** Cored concrete masonry, nominal 8-inch thick wall with one unit in wall thickness and with 62% minimum of solid material in each unit, load bearing (80 psi). Fire endurance: 2 1/2 hours.

**Table 1.1.5; Item W-10-M-11:** Cored concrete masonry, nominal 10-inch thick wall with two units in wall thickness and a 2-inch air space, load bearing (80 psi). The units are essentially the same as item W-8-M-82. Fire endurance: 3 1/2 hours.

These walls show 1-hour greater fire endurance by the addition of the 2-inch air space.

**Rule 4: The farther an air gap or cavity is located from the exposed surface, the more beneficial is its effect on the fire endurance.**

Radiation dominates the heat transfer across an air gap or cavity and it is markedly higher where the temperature is higher. The air gap or cavity is thus a poor insulator if it is located in a region that attains high temperatures during fire exposure.

Some of the clay tile designs take advantage of these factors. The double cell design, for instance, insures that there is a cavity near the unexposed face. Some floor/ceiling assemblies have air gaps or cavities near the top sur-
face and these enhance their thermal performance.

**Rule 5:** The fire endurance of a construction cannot be increased by increasing the thickness of a completely enclosed air layer.

Harmathy notes that there is evidence that if the thickness of the air layer is larger than about 1/2 inch, the heat transfer through the air layer depends only on the temperature of the bounding surfaces, and is practically independent of the distance between them. This rule is not applicable if the air layer is not completely enclosed, i.e., if there is a possibility of fresh air entering the gap at an appreciable rate.

**Rule 6:** Layers of materials of low thermal conductivity are better utilized on that side of the construction on which fire is more likely to happen.

As in Rule 4, the reason lies in the heat transfer process, though the conductivity of the solid is much less dependent on the ambient temperature of the materials. The low thermal conductor creates a substantial temperature differential to be established across its thickness under transient heat flow conditions. This rule may not be applicable to materials undergoing physical-chemical changes accompanied by significant heat absorption or heat evolution.

**Rule 7:** The fire endurance of asymmetrical construction—constructions that are not identical on both sides of their central line—depends on the direction of heat flow.

This rule is a consequence of Rules 4 and 6 as well as other factors. This rule is useful in determining the relative protection of corridors and stairwells from the surrounding spaces. In addition, there are often situations where a fire is more likely, or potentially more severe, from one side or the other.

**Rule 8:** The presence of moisture, if it does not result in explosive spalling, increases the fire endurance.

The flow of heat into an assembly is greatly hindered by the release and evaporation of the moisture found within cementitious materials such as gypsum, Portland cement, or magnesium oxychloride. Harmathy has shown that the gain in fire endurance may be as high as 8 percent for each percent (by volume) of moisture in the construction. It is the moisture chemically bound within the construction material at the time of manufacture or processing that leads to increased fire endurance. There is no direct relationship between the relative humidity of the air in the pores of the material and the increase in fire endurance.

Under certain conditions there may be explosive spalling of low permeability cementitious materials such as dense concrete. In general, one can assume that extremely old concrete has developed enough minor cracking that this factor should not be significant.

**Rule 9:** Load-supporting elements, such as beams, girders and joists, yield higher fire endurances when subjected to fire endurance tests as parts of floor, roof, or ceiling assemblies than they would when tested separately.

One of the fire endurance test criteria is the ability of a load-supporting element to carry its intended live and dead load. The element will be deemed to have failed when the load can no longer be supported.

Failure usually results for two reasons. Some materials, particularly steel and other metals, lose much of their structural strength at elevated temperatures. Physical deflection of the supporting element, due to decreased strength or thermal expansion, causes a redistribution of the load forces and stresses throughout the element. Structural failure often results because the supporting element is not designed to carry the redistributed load.

Roof, floor, and ceiling assemblies may have primary (e.g., beams) and secondary (e.g., floor joists) structural members. Since the primary load-supporting elements span the largest distances, their deflection becomes significant at a stage when the strength...
of the secondary members (including the roof or floor surface) is hardly affected by the heat. As the secondary members follow the deflection of the primary load-supporting element, an increasingly larger portion of the load is transferred to the secondary members.

When load-supporting elements are tested separately, the imposed load is constant and equal to the design load throughout the test. By definition, no distribution of the load is possible because the element is being tested by itself. Without any other structural members to which the load could be transferred, the individual elements cannot yield a higher fire endurance than they do when tested as parts of a floor, roof or ceiling assembly.

Rule 10: The load-supporting elements (beams, girders, joists, etc.) of a floor, roof, or ceiling assembly can be replaced by such other load-supporting elements that, when tested separately, yielded fire endurance not less than that of the assembly.

This rule depends on Rule 9 for its validity. A beam or girder, if capable of yielding a certain performance when tested separately, will yield an equally good or better performance when it forms a part of a floor, roof, or ceiling assembly. It must be emphasized that the supporting element of one assembly must not be replaced by the supporting element of another assembly if the performance of this latter element is not known from a separate (beam) test. Because of the load-reducing effect of the secondary elements that results from a test performed on an assembly, the performance of the supporting element alone cannot be evaluated by simple arithmetic. This rule also indicates the advantage of performing separate fire tests on primary load-supporting elements.

Illustration of Harmathy's Rules

Harmathy provided one schematic figure that illustrated his Rules. It should be useful as a quick reference to assist in applying his Rules. (See Figure IV.)

Example Application of Harmathy's Rules

The following examples, based in whole or in part upon those presented in Harmathy's paper (35), show how the Rules can be applied to practical cases.

Example 1

Problem

A contractor would like to keep a partition that consists of a 3 3/4 inch thick layer of red clay brick, a 1 1/4 inch thick layer of plywood, and a 3/8-inch thick layer of gypsum wallboard, at a location where 2-hour fire endurance is required. Is this assembly capable of providing a 2-hour protection?

Solution

(1) This partition does not appear in the tables in Appendix A.

(2) Bricks of this thickness yield fire endurance of approximately 75 minutes (Table 1.1.2, Item W-4-M-2).

(3) The 1 1/4 inch thick plywood has a finish rating of 30 minutes.

(4) The 3/8-inch gypsum wallboard has a finish rating of 10 minutes.

(5) Using the recommended values from the tables and applying Rule 1, the fire endurance (FI) of the assembly is larger than the sum of the individual layers, or

\[ FI > 75 + 30 + 10 = 115 \text{ minutes} \]

Discussion

This example illustrates how the tables in Appendix A can be utilized to determine the fire resistance of assemblies not explicitly listed.

Example 2

Problem

(1) A number of buildings to be rehabilitated have the same type of roof slab that is supported with different structural elements.

(2) The designer and contractor would like to determine whether or not this roof slab is capable of yielding a 2-hour fire endurance. According to a rigorous interpretation of ASTM E 119, however, only the roof assembly, including the roof slab as well as the cover and the supporting elements, can be subjected to a fire test. Therefore, a fire endurance classification cannot be issued for the slabs separately.

(3) The designer and contractor believe this slab will yield a 2-hour fire endurance.
fire endurance even without the cover, and any beam of at least 2-hour fire endurance will provide satisfactory support. Is it possible to obtain a classification for the slab separately?

Solution

(1) The answer to the question is yes.

(2) According to Rule 10, it is not contrary to common sense to test and classify roofs and supporting elements separately. Furthermore, according to Rule 2, if the roof slabs actually yield a 2-hour fire endurance, the endurance of an assembly, including the slabs, cannot be less than 2 hours.

(3) The recommended procedure would be to review the tables to see if the slab appears as part of any tested roof or floor/ceiling assembly. The supporting system can be regarded as separate from the slab specimen, and the fire endurance of the assembly listed in the table is at least the fire endurance of the slab. There would have to be an adjustment for the weight of the roof cover in the allowable load if the test specimen did not contain a cover.

(4) The supporting structure or element would have to have at least a 2-hour fire endurance when tested separately.

Discussion

If the tables did not include tests on assemblies that contained the slab, one procedure would be to assemble the roof slabs on any convenient supporting system (not regarded as part of the specimen) and to subject them to a load that, besides the usually required superimposed load, includes some allowances for the weight of the cover.

\[ t = \text{fire endurance} \]
Example 3

Problem

A steel joist floor/ceiling assembly is known to have yielded a fire endurance of 1 hour and 35 minutes. At a certain location, a 2-hour endurance is required. What is the most economical way of increasing the fire endurance by at least 25 minutes?

Solution

(1) The most effective technique would be to increase the ceiling plaster thickness. Existing coats of paint would have to be removed and the surface properly prepared before the new plaster could be applied. Other materials (e.g., gypsum wallboard) could also be considered.

(2) There may be other techniques based on other principles, but an examination of the drawings would be necessary.

Discussion

(1) The additional plaster has at least three effects:

   a) The layer of plaster is increased and thus there is a gain of fire endurance (Rule 1).

   b) There is a gain due to shifting the air gap farther from the exposed surface (Rule 4).

   c) There is more moisture in the path of heat flow to the structural elements (Rules 7 and 8).

(2) The increase in fire endurance would be at least as large as that of the finish rating for the added thickness of plaster. The combined effects in (1) above would further increase this by a factor of 2 or more, depending upon the geometry of the assembly.

Example 4

Problem

The fire endurance of item W-10-M-1 in Table 1.1.5 is 4 hours. This wall consists of two 3 3/4 inch thick layers of structural tiles separated by a 2-inch air gap and 3/4-inch Portland cement plaster or stucco on both sides. If the actual wall in the building is identical to item W-10-M-1 except that it has a 4-inch air gap, can the fire endurance be estimated at 5 hours?

Solution

The answer to the question is no for the reasons contained in Rule 5.

Example 5

Problem

In order to increase the insulating value of its precast roof slabs, a company has decided to use two layers of different concretes. The lower layer of the slabs, where the strength of the concrete is immaterial (all the tensile load is carried by the steel reinforcement), would be made with a concrete of low strength but good insulating value. The upper layer, where the concrete is supposed to carry the compressive load, would remain the original high strength, high thermal conductivity concrete. How will the fire endurance of the slabs be affected by the change?

Solution

The effect on the thermal fire endurance is beneficial:

(1) The total resistance to heat flow of the new slabs has been increased due to the replacement of a layer of high thermal conductivity by one of low conductivity.

(2) The layer of low conductivity is on the side more likely to be exposed to fire, where it is more effectively utilized according to Rule 6. The layer of low thermal conductivity also provides better protection for the steel reinforcement, thereby extending the time before reaching the temperature at which the creep of steel becomes significant.

3.3 "Thickness Design" Strategy

The "thickness design" strategy is based upon Harmathy's Rules 1 and 2. This design approach can be used when the construction materials have been identified and measured, but the specific assembly cannot be located within the tables. The tables should be surveyed again for thinner walls of like material and construction detail that have yielded the desired or greater fire endurance. If such an assembly can be found, then the thicker walls in the building have more than enough fire resistance. The thickness of the walls thus becomes the principal concern.

This approach can also be used for floor/ceiling assemblies provided the assembly will support the loading required for fire endurance testing of the subject assembly. However, the thickness of the cover and the slab will become a central concern. The fire resistance of the untested assembly will be at least the

Cover: the protective layer or membrane of material that slows the flow of heat to the structural elements.
fire resistance of an assembly listed in the table having a similar design but with less cover or thinner slabs. For other structural elements (e.g., beams and columns), the element listed in the table must also be of a similar design but with less cover thickness.

3.4 Evaluation of Doors

A separate section on doors is included in this Guideline because the process for evaluation presented below differs from those suggested previously for other building elements. The impact of unprotected openings or penetrations in fire-resistant assemblies has been discussed in Section 2.3 and the importance of door performance on life safety has been stressed. Consistent with this, it is sufficient to note here that improperly or inadequately protected door openings will likely lead to failure of the wall in which they are installed under actual fire conditions.

In all cases, local code requirements for opening protection should be carefully evaluated since many (but not all) 1-hour wall assemblies, for example, require only 20-minute-rated doors to be used. Thus, use of a 1-hour rated fire door assembly under such conditions would present an unwarranted economic hardship.

For other types of building elements (e.g., beams, columns), the tables in Appendix A can be used to establish a minimum level of fire performance, eliminating the need for a fire test. For doors, however, this cannot be done. The data contained in Appendix A, "Table 5.1, Resistance of Doors to Fire Exposure," and Appendix B, "Upgrading the Fire Resistance of Wood Panel Doors," only can provide guidance as to whether a successful fire test is even feasible.

For example, a door required to have 1-hour fire resistance is noted in the tables as providing only 5 minutes. The likelihood of achieving the required 1 hour, even if the door is upgraded, is remote. The ultimate need for replacement of the doors is reasonably clear, and the expense and time needed for testing can be saved. However, if the performance documented in the table is near or in excess of what is being required, then a fire test should be conducted. The test documentation can then be used as evidence of compliance with the required level of performance.

The table entries cannot be used as the sole proof of performance of the door in question because there are other variables that could measurably affect fire performance. The wood may have become embrittled over the years, or multiple coats of flammable varnish could have been added. Minor deviations in the internal construction of a door can also result in significant differences in performance. Methods of securing inserts in panel doors can vary. The major non-destructive method of analysis, an x-ray, often cannot provide the necessary detail. It is for these, and similar reasons, that a fire test may still be necessary.

It is often possible to upgrade the fire performance of an existing door. Existing and modified doors can be evaluated side-by-side in a single series of fire tests, where the failure of the unmodified door is expected. Because doors upgraded after an initial failure must be tested again, the side-by-side approach can save time and money.

The most common ways that the fire resistance of door assemblies is reduced are: the presence of ventilating elements, including transoms; the presence of plain, non-fire-resistant glass; insufficient thickness or poor condition of plywood door panels and panel inserts; and the improper fit of a door in its frame.

Approaches to solving these problems, as shown in Figure V and Appendix B, are as follows:

- Permanently sealing ventilating elements, such as transoms or ventilation openings in doors, and upgrading their fire resistance to match that of their door assemblies, unless they can be made to close automatically when a fire threat is present. Note that the health and comfort consequences of sealing ventilating elements must be thoroughly evaluated before such work is performed.
Figure V. Door Modification Details
Replacing plain glass in doors, transoms and sidelights with approved or listed wired glass or a contemporary fire-resistant glazing product installed in an approved steel or wood frame (167).

Upgrading panel inserts either by replacing existing panel materials with materials of greater fire resistance (such as swapping an existing wood panel for a grain-printed or -painted inorganic product with the required fire resistance), using intumescent materials, or adding additional layers of material, such as gypsum wallboard, to the existing panel to enhance fire resistance.

Problems related to the improper fit of doors in their frames can be significant because a fire-affected room may develop substantial positive pressure, causing flames, smoke, and hot gases to work their way through otherwise innocent-looking gaps between the door and frame. To mitigate these hazards, listed intumescent paint or gasketing may be applied to the edges of the door or door frame. These expand when exposed to fire, forming an effective fire-resistant seal at the door edges. The use of intumescent materials is widely accepted in fire door construction and fire door frame designs in the United States and Europe.

Because the interior construction of a door cannot be determined by a visual inspection, there is no absolute guarantee that the remaining doors are identical to the one(s) tested. But the same is true for doors constructed today, and reason and judgment must be applied. Doors that appear identical upon visual inspection can be weighed. If their weights are reasonably close, they can be assumed to be identical and to provide the same level of fire performance. Another approach is to fire test more than one door or to dismantle doors selected at random to determine if they have been constructed in the same manner. Original building plans showing door details or other records showing that doors were purchased at one time or obtained from a single supplier can also be evidence of similar construction.

More often though, it is what is visible to the eye that is most significant. The investigator should carefully check the condition and fit of the door and frame and look for frames out of plumb or separating from the wall. Door closers, latches, and hinges must be examined to see that they function properly and are tightly secured. If these are in order and the door and frame have passed a full-scale test, there can be a reasonable basis for allowing the existing doors to remain. However, the importance of insureing satisfactory performance of door hardware cannot be overstated. Full-scale tests of door assemblies in which sufficient construction materials are present to provide needed fire endurance but that fail because of untimely door opening are well known to fire testing laboratories and engineers. See Figure V.

4 Summary

This section summarizes the various approaches and design solutions for fire resistance discussed in the preceding sections of the Guideline. The term "structural system" includes: frames, beams, columns, and other structural elements. Cover" is a protective layer of materials or membrane that slows the flow of heat to the structural elements. It cannot be stressed too strongly that the fire endurance of actual building elements can be greatly reduced or totally negated by removing part of the cover to allow pipes, ducts, or conduits to pass through the element. This must be repaired in the rehabilitation process.

The following approaches shall be considered equivalent:
4.1 Application for Listed Building Elements

The fire resistance of a building element can be established from the tables in Appendix A. This is subject to the following limitations:

- The building elements in the rehabilitated building are constructed of the same materials with the same nominal dimensions as stated in the tables.
- All penetrations in the building element or its cover for services such as electricity, plumbing, and HVAC are treated in a manner consistent with current practices for new construction, using methods tested and documented for their fire endurance and anticipated durability. Descriptions of many such products and methods are available in fire resistance reference handbooks.
- The effects of age and deterioration are repaired so that the building element is sound and the original thickness of all components, particularly covers and floor slabs, is maintained.

This approach essentially follows the approach taken by the model codes, where a material or assembly must be listed in an acceptable publication for a given fire resistance rating to be recognized and accepted.

4.2 Application for Unlisted Building Elements

The fire resistance of a building element that does not explicitly appear in the tables in Appendix A can be established if one or more elements of same design but different dimensions have been listed in the tables in Appendix A. For walls, the existing element must be thicker than the one listed. For floor/ceiling assemblies, the assembly listed in the table must have the same or less cover and the same or thinner slab constructed of the same material as the actual floor/ceiling assembly. For other structural elements, the element listed in the table must be of a similar design but with less cover thickness. The fire resistance in all instances shall be the fire resistance recommended in the table. This is subject to the following limitations:

- The actual element in the rehabilitated building is constructed of the same materials as listed in the table. Only the following dimensions may vary from those specified: for walls, the overall thickness must exceed that specified in the table; for floor/ceiling assemblies, the thickness of the cover and the slab must be greater than or equal to that specified in the table; for other structural elements, the thickness of the cover must be greater than that specified in the table.
- All penetrations in the building element or its cover for services such as electricity, plumbing, or HVAC are treated in a manner consistent with current practices for new construction using methods tested and documented for their fire endurance and anticipated durability. Descriptions of many such products and methods are available in fire resistance reference handbooks.
- The effects of age and wear and tear are repaired so that the building element is sound and the original thickness of all components, particularly covers and floor slabs, is maintained.

This approach is an application of the "thickness design" concept presented in Section 3.3. There should be many instances when a thicker building element was utilized than the one listed in the tables in Appendix A. This Guideline recognizes the inherent superiority of a thicker design. Note: "thickness design" for floor/ceiling assemblies and structural elements refers to cover and slab thickness rather than total thickness.

The "thickness design" concept is essentially a special case of Harmathy’s Rules 1 and 2, where the source of data is Appendix A. If other sources are used, it must be in connection with the approach below.
4.3 General Application

The fire resistance of building elements can be established by applying Harmathy’s Ten Rules of Fire Endurance Rating as set forth in Section 3.2, subject to the following:

- The data from the tables can be utilized subject to the limitations in 4.2, above.
- Test reports from recognized journals or published papers can be used to support data utilized in applying Harmathy’s Rules.
- Calculations utilizing recognized and well established computational techniques can be used in applying Harmathy’s Rules. These include, but are not limited to, analysis of heat flow, mechanical properties, deflections, and load bearing capacity.
Appendix A—Fire Rating Tables

Introduction

The tables and histograms that follow are to be used only within the analytical framework described in this Guideline.

Histograms precede any table with ten or more entries. The use and interpretation of the histograms is explained in Section 2, above.

The table format is similar to the one used by the model codes. Figure VI below, taken from an entry in Table 1.1.2, explains the column headings:

- **Item Code.** This column contains the item code for each building element. The code consists of a four-place series, such as W-4-M-50, where:
  - **W** = type of building element; **F** = floors, etc.
  - **4** = the building element thickness rounded down to the nearest one-inch increment (for example, 4 5/8" is rounded off to 4").
  - **M** = the general type of material from which the building element is constructed; **M** = masonry, **W** = wood, etc.
  - **50** = the sequence number of the particular building element in a table.

- **Thickness.** This column identifies the dimension with the greatest impact on fire resistance. The critical dimension for walls (the example shown here) is thickness, but it differs for other building elements. For instance, the critical dimension for beams is depth and for some floor/ceiling assemblies it is membrane thickness. The dimension shown is the one measured at the time of actual testing to within ±1/8-inch tolerance. The thickness includes facings when they are part of the wall construction.

- **Construction Details.** This column provides a brief description of the building element.

- **Performance.** This column is subdivided into two columns in most tables. The first is labeled "Load" and either lists the load that the building element was subjected to during the fire test or refers to a note at the bottom of the table that provides information on the load or other significant details. If the building element was not subjected to a load during the test, the entry will be "n/a" for "not applicable." The second column is labeled "Time" and denotes the actual fire endurance time observed in the fire test.

- **Reference Number.** This column refers to the 1942 National Bureau of Standards publication, Building Material Standard 92, "Fire-Resistance Classifications of Building Constructions" (1). The column is subdivided into three parts: Pre-BMS-92, BMS-92, and Post BMS-92. Table entries refer to the number of the entry in the bibliography containing the original source reference for the test data.

- **Notes.** The entries in this column refer to notes at the end of the table that contain a more detailed explanation of certain aspects of the test. In some tables, note numbers also appear under the headings "Construction Details" and "Load."

- **Rec Hours.** This column lists the recommended fire endurance rating, in hours or minutes, of the subject building element. This rating is always less than or equal to the rating under the "Time" column.

Table 1.1.1—Notes
Masonry Walls, 0" to less than 4" thick

1. Failure mode—flame thru.
2. Passed 2-hr fire test (Grade “C” fire res.—British).
3. Passed hose stream test.
5. Tested at NBS under ASASpec. No. A2-1934 (ASTM C-19-33) except that hose stream testing where carried out was run on test specimens exposed for full test duration, not for a reduced period as is contemporarily done.
6. Failure by thermal criteria—maximum temperature rise 181ºC (325ºF).
8. Hose stream—pass.
9. Specimen removed prior to any failure occurring.
10. Failure mode—collapse.
11. For clay tile walls, unless the source or density of the clay can be positively identified or determined, it is suggested that the lowest hourly rating for the fire endurance of a clay tile partition of that thickness be followed. Identified sources of clay showing longer fire endurance can lead to longer time recommendations.
12. See appendix for construction and design details for clay tile walls.
13. Load—80 psi for gross wall area.

| 14. One cell in wall thickness. |
| 15. Two cells in wall thickness. |
| 16. Double shells plus one cell in wall thickness. |
| 17. One cell in wall thickness, cells filled with broken tile, crushed stone, slag cinders or sand mixed with mortar. |
| 18. Dense hard-burned clay or shale tile. |
| 19. Medium-burned clay tile. |
| 20. Not less than 5/8" thickness of 1:3 sanded gypsum plaster. |
| 21. Units of not less than 30% solid material. |
| 22. Units of not less than 40% solid material. |
| 23. Units of not less than 50% solid material. |
| 24. Units of not less than 45% solid material. |
| 25. Units of not less than 60% solid material. |
| 26. All tiles laid in portland cement-lime mortar. |
| 27. Blocks laid in 1:3 sanded gypsum mortar voids in blocks not to exceed 30%. |
| 28. Units of expanded slag or pumice aggregates. |
| 29. Units of crushed limestone, blast furnace slag, cinders and expanded clay or shale. |
| 30. Units of calcareous sand and gravel. Coarse aggregate, 60% or more calcite and dolomite. |

Note 39, Table 1.1.1. Designs of tiles used in fire-test partitions.

The four types of construction used in fire-test partitions.
Table 1.1.1—Notes, continued
31. Units of siliceous sand and gravel. 90% or more quartz, chert, or flint.
32. Unit at least 49% solid.
33. Unit at least 62% solid.
34. Unit at least 65% solid.
35. Unit at least 73% solid.
36. Ratings based on one unit and one cell in wall thickness.
37. Minimum of 1/2”—1:3 sanded gypsum plaster.
38. Non-load bearing.

### Table 1.1.2—Notes

- **Masonry Walls, 4" to less than 6" thick**

2. Failure mode—maximum temperature rise.
3. Tested at NBS under ASASpec. No. 42–1934 (ASTM C-19-53) except that hose stream testing where carried out was run on test specimens exposed for full test duration, not for a reduced period as is contemporarily done.
4. For clay tile walls, unless the source of the clay can be positively identified, it is suggested that the most pessimistic hour rating for the fire endurance of a clay tile partition of that thickness be followed. Identified sources of clay showing longer fire endurance can lead to longer time recommendations.
5. See appendix for construction and design details for clay tile walls.
6. Failure mode—flame thru or crack formation showing flames.
7. Hole formed at 25 minutes; partition collapsed at 42 minutes on removal from furnace.
8. Failure mode—collapse.
Table 1.1.2—Notes, continued

9. Hose stream pass.
10. Hose stream hole formed in specimen.
11. Load—80 psi for gross wall cross-sectioned area.
12. One cell in wall thickness.
13. Two cells in wall thickness.
14. Double cells plus one cell in wall thickness.
15. One cell in wall thickness, cells filled with broken tile, crushed stone, slag, cinders, or sand mixed with mortar.
16. Dense hard-burned clay or shale tile.
17. Medium-burned clay tile.
18. Not less than 5/8” thickness of 1:3 sanded gypsum plaster.
19. Units of not less than 30% solid material.
20. Units of not less than 40% solid material.
21. Units of not less than 50% solid material.
22. Units of not less than 45% solid material.
23. Units of not less than 60% solid material.
24. All tiles laid in portland cement-lime mortar.
25. Minimum 1/2” of 1:3 sanded gypsum plaster.
26. Laid in 1:3 sanded gypsum mortar. Voids in hollow units not to exceed 30%.
27. Units of expanded slag or pumice aggregate.
28. Units of crushed limestone, blast furnace slag, cinders, and expanded clay or shale.
29. Units of calcareous sand and gravel. Coarse aggregate, 60% or more calcite and dolomite.
30. Units of siliceous sand and gravel. 90% or more quartz, chert, or flint.
31. Unit at least 49% solid.
32. Unit at least 62% solid.
33. Unit at least 65% solid.
34. Unit at least 73% solid.
35. Ratings based on one unit and one cell in wall thickness.

Note 36, Table 1.1.2. Designs of tiles used in fire-test partitions.

The four types of construction used in fire-test partitions.

</table>
Table 1.1.3—Notes
Masonry Walls, 6” to less than 8” thick
1. Tested at NBS under ASASpec. No. A2–1934 (ASTM C-19-53) except that hose stream testing where carried out was run on test specimens exposed for full test duration, not for a reduced period as is contemporarily done.
2. Failure by thermal criteria—maximum temperature rise.
3. For clay tile walls, unless the source or density of the clay can be positively identified or determined, it is suggested that the lowest hourly rating for the fire endurance of a clay tile partition of that thickness be followed. Identified sources of clay showing longer fire endurance can lead to longer time recommendations.
4. See note 55 for construction and design details for clay tile walls.
6. Failure mode—collapse.
7. Collapsed on removal from furnace @ 1 hour 9 minutes.
9. Hose stream—passed.
10. No end point met in test.
11. Wall collapsed at 1 hour 28 minutes.
12. One cell in wall thickness.
13. Two cells in wall thickness.
14. Double shells plus one cell in wall thickness.
15. One cell in wall thickness, cells filled with broken tile, crushed stone, slag, cinders, or sand mixed with mortar.
16. Dense hard-burned clay or shale tile.
17. Medium-burned clay tile.
18. Not less than 5/8” thickness of 1:3 sanded gypsum plaster.
19. Units of not less than 30% solid material.

### Table 1.1.4—Notes
#### Masonry Walls, 8” (200 mm) to less than 10” (250 mm) thick

2. One unit in wall thickness.
3. Two units in wall thickness.
4. Two or three units in wall thickness.
5. Two cells in wall thickness.
6. Three or four cells in wall thickness.
7. Four or five cells in wall thickness.
8. Five or six cells in wall thickness.
9. Minimum % of solid material in units: 40%.
10. Minimum % of solid material in units: 43%.
11. Minimum % of solid material in units: 46%.
12. Minimum % of solid material in units: 48%.
13. Minimum % of solid material in units: 49%.
14. Minimum % of solid material in units: 45%.
15. Minimum % of solid material in units: 51%.
16. Minimum % of solid material in units: 53%.
17. Not less than 5/8” thickness of 1:3 sanded gypsum plaster.
18. Noncombustible or no members framed into wall.
19. Combustible members framed into wall.
20. Load: 80 psi for gross cross-sectional area of wall.
22. Failure mode thermal.
23. British test.
24. Passed all criteria.
25. Failed by sudden collapse with no preceding signs of impending failure.
26. One cell in wall thickness.
27. Two cells in wall thickness.
28. Three cells in wall thickness.

### Table 1.1.5—Notes  
**Masonry Walls, 10" to less than 12" thick**

2. One unit in wall thickness.
3. Two units in wall thickness.
4. Two or three units in wall thickness.
5. Two cells in wall thickness.
6. Three or four cells in wall thickness.
7. Four or five cells in wall thickness.
8. Five or six cells in wall thickness.
9. Minimum % of solid material in units: 40%.
10. Minimum % of solid material in units: 43%.
11. Minimum % of solid material in units: 46%.
12. Minimum % of solid material in units: 48%.
13. Minimum % of solid material in units: 49%.
14. Minimum % of solid material in units: 45%.
15. Minimum % of solid material in units: 51%.
16. Minimum % of solid material in units: 53%.
17. Not less than 5/8" thickness of 1:3 sanded gypsum plaster.
18. Noncombustible or no members framed into wall.
19. Combustible members framed into wall.
20. Load: 80 psi for gross cross-sectional area.
22. Failure mode—thermal.
23. British test.
24. Passed all criteria.
25. Failed by sudden collapse with no preceding signs of impending failure.
26. One cell in wall thickness.
27. Two cells in wall thickness.
28. Three cells in wall thickness.
29. Minimum % of solid material in concrete units: 52%.
30. Minimum % of solid material in concrete units: 54%.
31. Minimum % of solid material in concrete units: 55%.
32. Minimum % of solid material in concrete units: 57%.
33. Minimum % of solid material in concrete units: 60%.
34. Minimum % of solid material in concrete units: 62%.
35. Minimum % of solid material in concrete units: 65%.
36. Minimum % of solid material in concrete units: 70%.
37. Minimum % of solid material in concrete units: 76%.
38. Not less than 1/2" of 1:3 sanded gypsum plaster.
39. Three units in wall thickness.
40. Concrete units made with expanded slag or pumice aggregates.
41. Concrete units made with expanded burned clay or shale, crushed limestone, air-cooled slag, or cinders.
42. Concrete units made with calcareous sand and gravel. Coarse aggregate, 60% or more calcite and dolomite.

### Table 1.1.6—Notes

**Masonry Walls, 12" to less than 14" thick**

2. One unit in wall thickness.
3. Two units in wall thickness.
4. Two or three units in wall thickness.
5. Two cells in wall thickness.
6. Three or four cells in wall thickness.
7. Four or five cells in wall thickness.
8. Five or six cells in wall thickness.
9. Minimum % of solid materials in units: 40%.
10. Minimum % of solid materials in units: 43%.
11. Minimum % of solid materials in units: 46%.
12. Minimum % of solid materials in units: 48%.
13. Minimum % of solid materials in units: 49%.
Table 1.1.6—Notes, continued

14. Minimum % of solid materials in units: 45%.
15. Minimum % of solid materials in units: 51%.
16. Minimum % of solid materials in units: 53%.
17. Not less than 5/8" thickness of 1:3 sanded gypsum plaster.
18. Noncombustible or no members framed into wall.
19. Combustible members framed into wall.
20. Load: 80 psi for gross area.
22. Failure mode—thermal.
23. British test.
24. Passed all criteria.
25. Failed by sudden collapse with no preceding signs of impending failure.
26. One cell in wall thickness.
27. Two cells in wall thickness.
28. Three cells in wall thickness.
29. Minimum % of solid material in concrete units: 52%.
30. Minimum % of solid material in concrete units: 54%.
31. Minimum % of solid material in concrete units: 55%.
32. Minimum % of solid material in concrete units: 57%.
33. Minimum % of solid material in concrete units: 60%.
34. Minimum % of solid material in concrete units: 62%.
35. Minimum % of solid material in concrete units: 65%.
36. Minimum % of solid material in concrete units: 70%.
37. Minimum % of solid material in concrete units: 76%.
38. Not less than 1/2" of 1:3 sanded gypsum plaster.
39. Three units in wall thickness.
40. Concrete units made with expanded slag or pumice aggregates.
41. Concrete units made with expanded burned clay or shale, crushed lime-stone, air-cooled slag, or cinders.
42. Concrete units made with calcareous sand and gravel. Coarse aggregate, 60% or more calcite and dolomite.
43. Concrete units made with siliceous sand and gravel. 90% or more quartz, chert, or flint.
44. Load: 160 psi of gross wall cross-sectional area.
45. Load: 120 psi of gross wall cross-sectional area.

### Table 1.1.7—Notes  
*Masonry Walls, 14" or more thick*

2. One unit in wall thickness.
3. Two units in wall thickness.
4. Two or three units in wall thickness.
5. Two cells in wall thickness.
6. Three or four cells in wall thickness.
7. Four or five cells in wall thickness.
8. Five or six cells in wall thickness.
9. Minimum % of solid materials in units: 40%.
10. Minimum % of solid materials in units: 43%.
Table 1.1.7—Notes, continued
11. Minimum % of solid materials in units: 46%.
12. Minimum % of solid materials in units: 48%.
13. Minimum % of solid materials in units: 49%.
14. Minimum % of solid materials in units: 45%.
15. Minimum % of solid materials in units: 51%.
16. Minimum % of solid materials in units: 53%.
17. Not less than 5/8" thickness of 1:3 sanded gypsum plaster.
18. Noncombustible or no members framed into wall.
19. Combustible members framed into wall.
20. Load: 80 psi for gross area.
22. Failure mode—thermal.
23. British test.
24. Passed all criteria.
25. Failed by sudden collapse with no preceding signs of impending failure.
26. One cell in wall thickness.
27. Two cells in wall thickness.
28. Three cells in wall thickness.
29. Minimum % of solid material in concrete units: 52%.
30. Minimum % of solid material in concrete units: 54%.
31. Minimum % of solid material in concrete units: 55%.
32. Minimum % of solid material in concrete units: 57%.
33. Minimum % of solid material in concrete units: 60%.
34. Minimum % of solid material in concrete units: 62%.
35. Minimum % of solid material in concrete units: 65%.
36. Minimum % of solid material in concrete units: 70%.
37. Minimum % of solid material in concrete units: 76%.
38. Not less than 1/2" of 1:3 sanded gypsum plaster.
39. Three units in wall thickness.
40. Concrete units made with expanded slag or pumice aggregates.
41. Concrete units made with expanded burned clay or shale, crushed lime-
    stone, air-cooled slag or cinders.
42. Concrete units made with calcareous sand and gravel. Coarse aggregate,
    60% or more calcite and dolomite.
43. Concrete units made with siliceous sand and gravel. 90% or more quartz,
    chert, or flint.

### Table 1.2.1—Notes

**Metal Frame Walls, 0" to less than 4" thick**

1. Failure mode—local temperature rise—back face.
2. 3/4" or 1" channel framing—hot-rolled or strip-steel channels.
3. Reinforcement is 4" square mesh of No. 6 wire welded at intersections (no channels).
4. Ratings are for any usual type of non-load-bearing metal framing providing 2" (or more) air space.

### General Note

The construction details of the wall assemblies are as complete as the source documentation will permit. Data on the method of attachment of facings and the gauge of steel studs was provided when known. The cross-sectional area of the steel stud can be computed, thereby permitting a reasoned estimate of actual loading conditions. For load-bearing assemblies, the maximum allowable stress for the steel studs has been provided in the table “Notes.” More often, it is the thermal properties of the facing materials, rather than the specific gauge of the steel, that will determine the degree of fire resistance. This is particularly true for non-bearing wall assemblies.

### Table 1.2.2—Notes

#### Metal Frame Walls, 4" to less than 6" thick

1. Failure mode—local back face temperature rise.
2. Ratings are for any usual type of non-bearing metal framing providing a minimum 2" air space.
3. Facing materials secured to lightweight steel studs not less than 3" deep.
4. Rating based on loading to develop a maximum stress of 7270 psi for net area of each stud.
5. Spacing of steel studs must be sufficient to develop adequate rigidity in the metal-lath or gypsum-plaster base.
6. As per note 4 but load/stud not to exceed 5120 psi.

### General Note

The construction details of the wall assemblies are as complete as the source documentation will permit. Data on the method of attachment of facings and the gauge of steel studs was provided when known. The cross-sectional area of the steel stud can be computed, thereby permitting a reasoned estimate of actual loading conditions. For load-bearing assemblies, the maximum allowable stress for the steel studs has been provided in the table “Notes.” More often, it is the thermal properties of the facing materials, rather than the specific gauge of the steel, that will determine the degree of fire resistance. This is particularly true for non-bearing wall assemblies.

</table>

### Table 1.2.3—Notes

**Metal Frame Walls, 6" to less than 8" thick**

1. Lightweight steel studs (minimum 3" deep) used. Stud spacing dependent on loading, but in each case, spacing is to be such that adequate rigidity is provided to the metal lath plaster base.

2. Load is such that stress developed in studs is not greater than 5120 psi calculated from net stud area.

### General Note

The construction details of the wall assemblies are as complete as the source documentation will permit. Data on the method of attachment of facings and the gauge of steel studs was provided when known. The cross-sectional area of the steel stud can be computed, thereby permitting a reasoned estimate of actual loading conditions. For load-bearing assemblies, the maximum allowable stress for the steel studs has been provided in the table “Notes.” More often, it is the thermal properties of the facing materials, rather than the specific gauge of the steel, that will determine the degree of fire resistance. This is particularly true for non-bearing wall assemblies.

Table 1.3.1—Notes
Wood Frame Walls, 0" to less than 4" thick

1. Achieved “Grade C” fire resistance (British).
2. Nominal 2 x 4 wood studs of No. 1 Common or better lumber set edgewise, 2 x 4 plates at top and bottom and blocking at mid-height of wall.
3. All horizontal joints in facing material backed by 2 x 4 blocking in wall.
4. Load = 360 psi of net stud cross-sectional area.
5. Facings secured with 6 d casing nails. Nail holes predrilled and 0.02”–0.03” smaller than nail diameter.
6. The wood-wool core is a pressed excelsior slab which possesses insulating properties similar to cellulosic insulation.

Table 1.3.2—Notes

Wood Frame Walls, 4” (100 mm) to less than 6” (150 mm) thick

1. All specimens 8’ or 8’8” x 10’4”—i.e., 1/2 of furnace size. See note 42 for design cross section.
2. Specimens tested in tandem (two per exposure).
3. Test per ASANo. A-2-1934 except where unloaded. Also, panels were of “half” size of furnace opening. Time value signifies a thermal failure time.
4. 2” x 4” studs, 16” O.C.; where 10’4”, blocking @ 2’4” height.
5. Facing 4’ x 8’, cement-asbestos board sheets 3/16” thick.
6. Sheathing (diagonal) 25/32” x 5 1/2” on 1” x 6” pine.
7. Facing shingles—24” x 12” x 5/32” where used.
8. Asbestos felt—asphalt set between sheathing and shingles.
9. Load—30,500 lbs or 360 psi/stud where load was tested.
10. Walls were tested beyond achievement of first test end point. A load bearing time in excess of performance time indicates that although thermal criteria were exceeded load bearing ability continued.
11. Wall was rated for 1 hr combustible use in original source.
12. Hose stream test specimen. See table entry of similar design for recommended rating.
13. Rated 1 1/4 hr load bearing. Rated 1 1/2 hr non-load bearing.
15. Test terminated due to flame penetration.
16. Test terminated—local back face temperature rise.
17. Nominal 2” x 4” wood studs of No. 1 common or better lumber set edge-wise. 2” x 4” plates at top and bottom and blocking at mid-height of wall.
18. Cavity insulation consists of rock wool bats 1.0 lb/ft² of filled cavity area.
19. Cavity insulation consists of glass-wool bats 0.6 lb/ft² of filled cavity area.
20. Cavity insulation consists of blown-in forck wool 2.0 lb/ft² of filled cavity area.
21. Mix proportions for plastered walls as follows: first ratio indicates scratch coat mix, weight of dry plaster to dry sand; second ratio indicates brown coat mix.
22. “Neat” plaster is taken to mean unsanded wood-fiber gypsum plaster.
23. Load = 360 psi of net stud cross-sectional area.
24. Rated as non-load bearing.
25. Nominal 2” x 4” studs per note 17, spaced at 16” on center.
26. Horizontal joints in facing material supported by 2” x 4” blocking within wall.
27. Facings secured with 6 d casing nails. Nail holes predrilled and were 0.02”–0.03” smaller than nail diameter.
28. Cavity insulation consists of mineral wool bats weighing 2 lb/ft² of filled cavity area.
29. Interior wall face exposed to fire.
30. Exterior wall face exposed to fire.
31. Nominal 2” x 4” studs of yellow pine or Douglas fir spaced 16” on center in a single row.
32. Studs as in note 31 except double row, with studs in rows staggered.
33. Six roofing nails with metal-lath pads around heads to each 16” x 48” lath.
34. Areas of holes less than 2 3/4% of area of lath.
35. Wood laths were nailed with either 3 d or 4 d nails, one nail to each bearing, and the end joining broken every 7th course.
36. 1/2” thick fiberboard plaster base nailed with 3 d or 4 d common wire nails spaced 4” x 6” on center.
37. 7/8” thick fiberboard plaster base nailed with 5 d common wire nails spaced 4” x 6” on center.
38. Mineral wool bats 1.05–1.25 lb/ft² with waterproofed-paper backing.
39. Blown-in mineral wool insulation, 2.2 lb/ft².
40. Mineral wool bats, 1.4 lb/ft² with waterproofed-paper backing.
41. Mineral wool bats, 0.9 lb/ft².
42. See wall design diagram, below.
43. Duplicate specimen of W-4-W-7, tested simultaneously with W-4-W-7 in 18 ft. test furnace.

### Table 1.3.3—Notes
Wood Frame Walls, 6"(150 mm) to less than 8" (200 mm) thick

1. Nominal 2 x 4 wood studs of No. 1 common or better lumber set edgewise.
   2 x 4 plates at top and bottom and blocking at mid-height of wall.

2. Mix proportions for plastered walls as follows: first ratio indicates scratch coat mix, weight of dry plaster to dry sand; second ratio indicates brown coat mix.

3. Load = 360 psi of net stud cross-sectional area.

4. Nominal 2 x 4 studs of yellow pine or Douglas fir spaced 16" in a double row, with studs in rows staggered.

5. Mineral wool bats, 0.19 lb/ft².

**Table 1.4.1—Notes**
Walls—Miscellaneous Materials, 0” to less than 4” thick

1. No failure reached at 1 hour.
2. These glass blocks are assumed to be solid based on other test data available for similar but hollow units that show significantly reduced fire endurance.
3. Minimum of 1/2” of 1:3 sanded gypsum plaster required to develop this rating.

### Table 1.5.1—Notes

**Finish Ratings—Inorganic Materials**

1. The finish rating is the time required to obtain an average temperature rise of 250°F, or a single point rise of 325°F, at the interface between the material being rated and the substrate being protected.

3. Mix proportions for plaster as follows: first ratio, dry weight of plaster to dry weight of sand for scratch coat; second ratio, plaster to sand for brown coat.

#### Table 1.5.2—Notes  
**Finish Ratings—Organic Materials**

1. The finish rating is the time required to obtain an average temperature rise of 250°F, or a single point rise of 325°F, at the interface between the material being rated and the substrate being protected.

3. Plaster ratios as follows: first ratio is for scratch coat, weight of dry plaster to weight of dry sand; second ratio is for the brown coat.

#### General Note

The finish rating of thinner materials, particularly thinner woods, have not been listed because the possible effects of shrinkage, warpage, and aging cannot be predicted.

### Table 2.1.3—Notes

**Reinforced Concrete Columns, Minimum Dimension 12” to less than 14”**

1. Failure mode—unspecified structural.

2. Group I—includes concrete having calcareous aggregate containing a combined total of not more than 10 percent of quartz, chert, and flint for the coarse aggregate.

   Group II—includes concrete having trap-rock aggregate applied without metal ties and also concrete having cinder, sandstone, or granite aggregate, if held in place with wire mesh or expanded metal having not larger than 4-in. mesh, weighing not less than 1.7 lb/ft<sup>2</sup>, placed not more than 1 in. from the surface of the concrete.

   Group III—includes concrete having cinder, sandstone, or granite aggregate tied with No. 5 gauge steel wire, wound spirally over the column section on a pitch of 8 in., or equivalent ties, and concrete having siliceous aggregates containing a combined total of 60 percent or more of quartz, chert, and flint, if held in place with wire mesh or expanded metal having not larger than 4-in. mesh, weighing not less than 1.7 lb/ft<sup>2</sup>, placed not more than 1 in. from the surface of the concrete.

3. Groupings of aggregates and ties are the same as for structural steel columns protected solidly with concrete, the ties to be placed over the vertical reinforcing bars and the mesh, where required, to be placed within 1 in. from the surface of the column.

Column A—working loads are assumed as carried by the area of the column inside of the lines circumscribing the reinforcing steel.

Column B—working loads are assumed as carried by the gross area of the column.

### Table 2.5.1.3—Notes (Steel Columns—Concrete Encasements, Minimum Dimension 8” to less than 10”)

1. Failure mode—collapse.

2. Group I—includes concrete having calcareous aggregate containing a combined total of not more than 10 percent of quartz, chert, and flint for the coarse aggregate.

Group II—includes concrete having trap-rock aggregate applied without metal ties and also concrete having cinder, sandstone, or granite aggregate, if held in place with wire mesh or expanded metal having not larger than 4-in. mesh, weighing not less than 1.7 lb/yd², placed not more than 1 in. from the surface of the concrete.

Group III—includes concrete having cinder, sandstone, or granite aggregate tied with No. 5 gauge steel wire, wound spirally over the column section on a pitch of 8 in., or equivalent ties, and concrete having siliceous aggregates containing a combined total of 60 percent or more of quartz, chert, and flint, if held in place with wire mesh or expanded metal having not larger than 4-in. mesh, weighing not less than 1.7 lb/yd², placed not more than 1 in. from the surface of the concrete.

Group IV—includes concrete having siliceous aggregates containing a combined total of 60 percent or more of quartz, chert, and flint, and ties with No. 5 gauge steel wire wound spirally over the column section on a pitch of 8 in., or equivalent ties.

Table 2.5.1.4—Notes
Steel Columns—Concrete Encasements, Minimum Dimension 10” to less than 12”

1. Tested under total restraint load to prevent expansion—minimum load 90 tons.
2. Failure mode—collapse.
3. Passed 2-hr fire test (Grade “C”—British).
4. Passed hose stream test.
5. Column tested and passed 3-hr grade fire resistance (British).
6. Column passed 3-hr fire test.
7. Column collapsed during hose stream testing.
8. Column passed 6-hr fire test.
9. Group I—includes concrete having calcareous aggregate containing a combined total of not more than 10 percent of quartz, chert, and flint for the coarse aggregate.

Group II—includes concrete having trap-rock aggregate applied without metal ties and also concrete having cinder, sandstone, or granite aggregate, if held in place with wire mesh or expanded metal having not larger than 4-in. mesh, weighing not less than 1.7 lb/ft², placed not more than 1 in. from the surface of the concrete.

Group III—includes concrete having cinder, sandstone, or granite aggregate tied with No. 5 gauge steel wire, wound spirally over the column section on a pitch of 8 in., or equivalent ties, and concrete having siliceous aggregates containing a combined total of 60 percent or more of quartz, chert, and flint, if held in place with wire mesh or expanded metal having not larger than 4-in. mesh, weighing not less than 1.7 lb/ft², placed not more than 1 in. from the surface of the concrete.

Group IV—includes concrete having siliceous aggregate containing a combined total of 60 percent or more of quartz, chert, and flint, and tied with No. 5 gauge steel wire wound spirally over the column section on a pitch of 8 in., or equivalent ties.

**Table 2.5.1.7—Notes**

Steel Columns—Concrete Encasements

Minimum Dimension 16" to less than 18"

1. Group I—includes concrete having calcareous aggregate containing a combined total of not more than 10 percent of quartz, chert, and flint for the coarse aggregate.

   Group II—includes concrete having trap-rock aggregate applied without metal ties and also concrete having cinder, sandstone, or granite aggregate, if held in place with wire mesh or expanded metal having not larger than 4-in. mesh, weighing not less than 1.7 lb/ft², placed not more than 1 in. from the surface of the concrete.

   Group III—includes concrete having cinder, sandstone, or granite aggregate tied with No. 5 gauge steel wire, wound spirally over the column section on a pitch of 8 in., or equivalent ties, and concrete having siliceous aggregates containing a combined total of 60 percent or more of quartz, chert, and flint, if held in place with wire mesh or expanded metal having not larger than 4-in. mesh, weighing not less than 1.7 lb/ft², placed not more than 1 in. from the surface of the concrete.

   Group IV—includes concrete having siliceous aggregate containing a combined total of 60 percent or more of quartz, chert, and flint, and tied with No. 5 gauge steel wire wound spirally over the column section on a pitch of 8 in., or equivalent ties.
Table 2.5.2.1—Notes
Steel Columns—Brick and Block Encasements
Minimum Dimension 10" to less than 12" (300 mm)

1. Failure mode—collapse.
2. Passed 2-hr fire test (Grade “C”—British).
3. Passed hose stream test.
4. Passed reload test.
5. Passed 2-hr fire exposure but collapsed immediately following hose stream test.

**Table 3.1—Notes**

1. British test.
2. Failure mode—local back face temperature rise.
3. Tested for grade “C” (2 hr) fire resistance.
4. Collapse imminent following hose stream.
5. Failure mode: flame-thru.
6. Void formed with explosive force and report.
7. Achieved grade “B” (4 hr) fire resistance (British).
8. Failure mode—collapse.
9. Test was run to 2 hrs, but specimen was partially supported by the furnace at 1 1/4 hrs.
10. Failure mode: average back face temperature.
11. Recommended endurance is for non-load-bearing performance only.
12. Floor maintained load-bearing ability to 2 hrs at which point test was terminated.
13. Test was run to 3 hrs at which time failure mode 2 (above) was reached in spite of crack formation at 29 min.
14. Tested for grade “A” (6 hr) fire resistance.
15. See drawing.
16. Load unspecified.
17. Total assembly thickness 5 1/2”. Three-inch thick-blocks of molded excelsior bonded with portland cement used as inserts with 2 1/2” cover (concrete) above blocks and 3/4” gypsum plaster below. Nine-inch-wide ribs containing reinforcing steel of unspecified size interrupted 20” wide segments of slab composite (i.e., plaster, excelsior blocks, concrete cover).

</table>
Table 3.2—Notes
Floor/Ceiling Assemblies—Steel Structural Elements

1. No protective membrane over structural steel.

2. Performance time indicates first end point reached; only several tests were continued to points where other failures occurred.

3. Load failure.

4. Thermal failure.

5. This is an estimated time to load bearing failure. The same joist and deck specimen was used for a later test with different membrane protection.

6. Test stopped at 3 hr to reuse specimen; no end point reached.

7. Test stopped at 1 hr to reuse specimen; no end point reached.

8. All plaster used = gypsum.

9. Specimen size—18' x 13 1/2'. Floor deck base material—1/4' x 18' steel plate welded to I beam.

10. I beams—24' O.C.

11. I beams—48' O.C.

12. Apply to open web joints, pressed steel joists, or rolled steel beams, which are not stressed beyond 18,000 lb/in² in flexure for open-web pressed, or light rolled steel joists and 20,000 lb/in² for American standard or heavier rolled beams.

13. Ratio of weight of portland cement to fine and coarse aggregates combined for floor slabs shall not be less than 1:6 1/2.

14. Plaster for ceiling shall be applied on metal lath that shall be tied to supports to give the equivalent of single No. 18 gauge steel wires 5' O.C.

15. Load: maximum fiber stress in steel not to exceed 16,000 psi.

16. Prefabricated units 2 ft. wide with length equal to the span, composed of 2 pieces of No. 18 gauge formed steel welded together to give 4 longitudinal cells.

17. Depth not less than 3" and distance between cells not less than 2".

18. Ceiling: metal lath tied to furring channels secured to runner channels hung from cellular steel.

19. Load: rolled steel supporting beams and steel plate base shall not be stressed beyond 20,000 psi in flexure. Formed steel (with wide upper flange) construction shall not be stressed beyond 16,000 psi.

20. Some type of expanded metal or woven wire shall be imbedded to prevent cracking in concrete flooring.

21. Ceiling plaster shall be on metal lath wired to rods or channels that are clipped or welded to steel construction. Lath shall be no smaller than 18 gauge steel wire and not more than 7" O.C.

22. The securing rods or channels shall be at least as effective as single 3/16" rods with 1" of their length bent over the lower flanges of beams with the rods or channels tied to this clip with 14 gauge iron wire.

### Table 3.3—Notes
*Floor/Ceiling Assemblies—Wood Joist*

1. Thickness indicates thickness of first membrane protection on ceiling surface.
2. Failure mode—flame thru.
3. Failure mode—collapse.
4. No end point reached at termination of test.
5. Failure imminent—test terminated.
7. Joist failure—17 min., flame thru—18 min., collapse—33 min.
12. Joists: 2" x 10" southern pine or Douglas fir; No. 1 common or better; subfloor: 3/4" wood sheathing diaphragm of asbestos paper, and finish of tongue and groove wood flooring.
13. Loadings: not more than 1000 psi maximum fiber stress in joists.
14. Perforations in gypsum lath are to be not less than 3/4" diameter with one perforation for not more than 16/in² diameter.
15. "Distemper" is a British term for a water-based paint such as whitewash or calcimine.

Table 3.4—Notes

Floor/Ceiling Assemblies—Hollow Clay Tile With Reinforced Concrete

1. A generalized cross section of this floor type follows. See figure below.
2. Failure mode—structural.
4. Failure mode—collapse.
5. Test stopped before any end points were reached.
6. A generalized cross section of this floor type follows. See figure below.
7. Failure mode—thermal; back face temperature rise.
8. Passed hose stream test.
10. Test stopped at 4 hrs before any end points were reached.
11. A generalized cross section of this floor type follows. See figure below.
13. Concrete in item 7 is P.C.-based but with crushed brick aggregates, while in item 8 river sand and river gravels are used with the P.C.
15. The 12” x 12” fire-clay tiles were laid end to end in rows spaced 2 1/2” or 4” apart. The reinforcing steel was placed between these rows and the concrete cast around them and over the tile to form the structural floor.

Table 4.1.2—Notes
Reinforced Concrete Beams, depth 12” to less than 14”

1. Qualified for 2-hr use. (Grade “C”—British) test included hose stream and
reload at 48 hours.

2. Load concentrated at mid-span.

4. British test—qualified for 6-hr use (Grade “A”).

5. See figure below.

6. See figure below.

7. See figure below.

8. See Table 4.1.3, Note 5.

**Table 4.1.3—Notes**

**Reinforced Concrete Beams, depth 14" to less than 16"**

1. Load concentrated at mid-span.
2. Achieved 6-hr fire rating (Class "A"—British).
3. See Figure.
4. See Figure.
5. Section 43.147 of the 1979 Edition of the Uniform Building Code Standards provides:

   "A restrained condition in fire tests, as used in this standard, is one in which expansion at the supports of a load-carrying element resulting from the effects of the fire is resisted by forces external to the element. An unrestrained condition is one in which the load-carrying element is free to expand and rotate at its support.

   "(R)estraint in buildings is defined as follows: Floor and roof assemblies and individual beams in buildings shall be considered restrained when the surrounding or supporting structure is capable of resisting the thermal expansion throughout the range of anticipated elevated temperatures. Construction not complying...is assumed to be free to rotate and expand and shall be considered unrestrained.

   "Restraint may be provided by the lateral stiffness of supports for floor and roof assemblies and intermediate beams forming part of the assembly. In order to develop restraint, connections must adequately transfer thermal thrusts to such supports. The rigidity of adjoining panels or structures shall be considered in assessing the capabilities of a structure to resist thermal expansion."

Because it is difficult to determine whether an existing building's structural system is capable of providing the required restraint, the lower hourly ratings of a similar, but unrestrained assembly have been recommended.

6. Hourly rating based upon Table 4.1.2, Item B-12-RC-2.

</table>
| D-42      | 1 5/8"              | Wood frame single lite door with sidelites and transom; includes proprietary fire resistant glazing | 66 min | - | 187 | - | 66 | 11. The doors reported in these tests represent the type contemporaries used as 20-minute solid core wood doors. The test results demonstrate the necessity of having wall anchored metal frames, minimum cleaners possible between door, frame, and stops. They also indicate the utility of long throw latches and the possible use of intumescent paints to seal doors to frames in event of a fire.  
12. Minimum working clearance and good latch closure are absolute necessities for effective containment for all such working door assemblies.  
13. Based on British tests.  
14. Failure at door-frame interface. |
Appendix B—Upgrading the Fire Resistance of Wood Panel Doors

This Appendix contains information from pages 28–34 of the English Heritage Technical Guidance Note, Timber Paneled Doors and Fire, on upgrading the fire resistance of wood panel doors (166). Twenty-eight panel door treatments are shown and the fire resistance (“result”) of each is stated in minutes.

The fire resistance data is based on tests performed in accordance with British Standard 476, Fire Tests on Building Materials and Structures. The actual fire resistance of each door treatment will vary with the door’s condition, the quality of its construction, and the hardware used. See Section 2.3 for additional information.

Test reference notations are composed of the initials of the test sponsor, the initials of the testing house, the test number, and the test date, such as EH/WFRC 55983 7/4/92, where:

- **EH** English Heritage
- **GLC** Greater London Council
- **HRPA** Historic Royal Palaces Agency
- **FRS** Fire Research Station
- **FITO** Fire Insurers Test Organisation
- **TRADA** Timber Research and Development Association
- **WFRC** Warrington Fire Research Center

Dimensions are shown in millimeters, where 1/8” = 3.2 mm, 1/4” = 6.4 mm, 3/8” = 9.5 mm, 1/2” = 12.7 mm, 5/8” = 15.9 mm, 3/4” = 19.0 mm, 7/8” = 22.2 mm, and 1” = 25.4 mm. Since 0.1 mm equals only 1/254 of an inch, conversions may be rounded to the nearest millimeter (1/25.4 of an inch).

This material is used with the permission of English Heritage, 23 Savile Row, London W1X 1AB, www.english_heritage.org.
